

# **Memory Management**

## Suresh Jamadagni

**Department of Computer Science** 

#### Slides Credits for all the PPTs of this course

- The slides/diagrams in this course are an adaptation,
   combination, and enhancement of material from the following resources and persons:
- 1. Slides of Operating System Concepts, Abraham Silberschatz, Peter Baer Galvin, Greg Gagne 9th edition 2013 and some slides from 10th edition 2018
- 2. Some conceptual text and diagram from Operating Systems Internals and Design Principles, William Stallings, 9th edition 2018
- 3. Some presentation transcripts from A. Frank P. Weisberg
- 4. Some conceptual text from Operating Systems: Three Easy Pieces, Remzi Arpaci-Dusseau, Andrea Arpaci Dusseau

**Swapping, Memory Allocation, Fragmentation** 

## Suresh Jamadagni

**Department of Computer Science** 

## **Swapping**

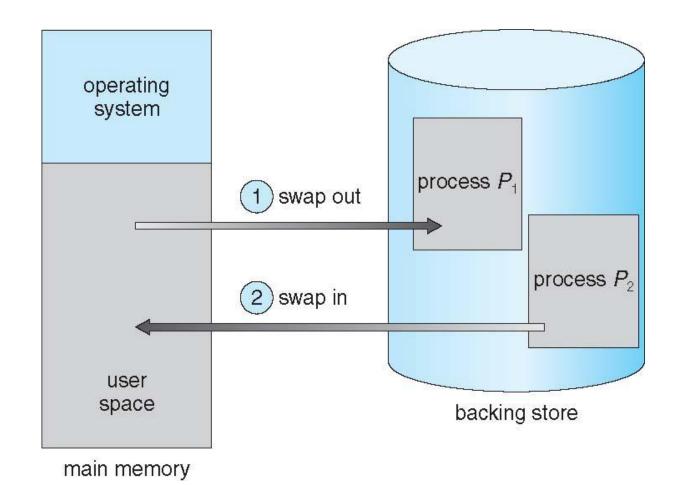

- PES UNIVERSITY ONLINE
- A process can be swapped temporarily out of memory to a backing store, and then brought back into memory for continued execution
  - Total physical memory space of processes can exceed physical memory
- Backing store fast disk large enough to accommodate copies of all memory images for all users;
   must provide direct access to these memory images
- Roll out, roll in swapping variant used for priority-based scheduling algorithms; lower-priority process is swapped out so higher-priority process can be loaded and executed
- Major part of swap time is transfer time; total transfer time is directly proportional to the amount of memory swapped
- System maintains a ready queue of ready-to-run processes which have memory images on disk

## **Swapping (Cont.)**

PES UNIVERSITY ONLINE

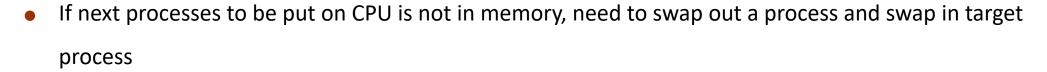

- Does the swapped out process need to swap back in to same physical addresses?
- Depends on address binding method
  - Plus consider pending I/O to / from process memory space
- Modified versions of swapping are found on many systems (i.e., UNIX, Linux, and Windows)
  - Swapping normally disabled
  - Started if more than threshold amount of memory allocated
  - Disabled again once memory demand reduced below threshold

# **Schematic View of Swapping**

### **Context Switch Time including Swapping**

- Context switch time can then be very high
- Let us consider a user process with size 100MB
- hard disk transfer rate of 50MB/sec
  - Swap out time=100MB/50MB per sec= 2 sec
  - Swap in in time is same as swap out time
  - Total context switch swapping component time = 4 seconds = swap in time + swap out time
- What will be the swap time for process with size 3GB? 60 secs
- Is it right to swap complete process?
- Can be reduced if size of memory to be swapped is reduced by knowing how much memory really being used
  - System calls to inform OS of memory use via request\_memory() and release\_memory()

### **Context Switch Time and Swapping (Cont.)**

PES UNIVERSITY ONLINE

- Other constraints as well on swapping
  - Pending I/O can't swap out as I/O would occur to wrong process
  - Or always transfer I/O to kernel space, then to process memory space
    - Known as double buffering, adds overhead
- Standard swapping not used in modern operating systems
  - But modified version common
    - Swap only when free memory extremely low

### **Swapping on Mobile Systems**

- Not typically supported
  - Flash memory is used rather than hard disks
    - Storage is a constraint for swapping
    - Limited number of writes are tolerated by flash memory
    - Poor throughput between flash memory and CPU on mobile platform
- Instead of swapping, other methods to free memory if memory is low
  - iOS asks apps to voluntarily relinquish allocated memory
  - Read-only data are removed system and are loaded if needed
  - Data that have been modified (such as the stack) are never removed.
  - Applications that fail to free up sufficient memory may be terminated by the operating system.

### **Swapping on Mobile Systems**

#### **Android OS**

- Does not support swapping
- Android terminates apps if low free memory, but first writes application state to flash for fast restart
- Both OSes support paging which will be discussed later

### **Contiguous Allocation**

- Main memory must accommodate both OS and user processes
- Memory needs to be allocated efficiently
- Contiguous allocation is one early method
- Main memory usually into two partitions:
  - Resident operating system, usually held in low memory with interrupt vector
  - User processes then held in high memory
  - Each process contained in single section of memory that is contiguous to the section containing the next process.

# **Contiguous Allocation**

Operating system

Application program

Lower address

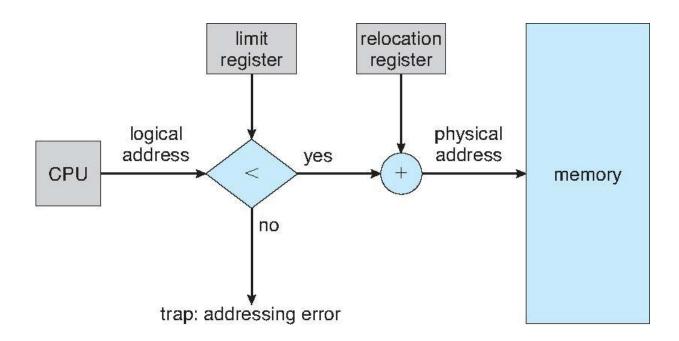

higher address

### **Contiguous Allocation (Cont.)**

- Relocation registers used to protect user processes from each other, and from changing operating-system code and data
  - Base register contains value of smallest physical address
  - Limit register contains range of logical addresses each logical address must be less than the limit register
  - MMU maps logical address dynamically
  - Can then allow actions such as kernel code being transient (it comes and goes as needed) and kernel/OS changing size during program execution.

### **Hardware Support for Relocation and Limit Registers**

When the CPU scheduler selects a process for execution, the dispatcher loads the relocation and limit registers with the correct values as part of the context switch.

### **Memory Protection**

- Every address generated by a CPU is checked against these registers, so possible to protect both the operating system and the other users' programs and data from being modified by this running process.
- The relocation-register scheme provides an effective way to allow the operating system's size to change dynamically.
  - This flexibility is desirable in many situations. For example, the operating system contains code and buffer space for device drivers. If a device driver is not currently in use, it makes little sense to keep it in memory; instead, it can be loaded into memory only when it is needed. Likewise, when the device driver is no longer needed, it can be removed and its memory allocated for other needs.

### **Multiple-partition allocation**

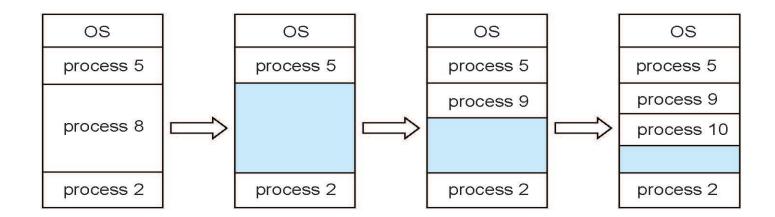

- Multiple-partition allocation
  - Divide memory into several fixed-size partitions.
    - Each partition may contain exactly one process
    - Degree of multiprogramming is bounded by number of partitions.
    - when a partition is free, a process is selected from the input queue and is loaded into the free partition
    - used by the IBM OS/360 operating system, but is no longer in use
  - Variable-partition sizes for efficiency (sized to a given process' needs)
    - This scheme keeps a table indicating which parts of memory are available/occupied
  - Hole block of available memory; holes of various size are scattered throughout memory

### Multiple-partition allocation (Cont.)

PES UNIVERSITY ONLINE

- When a process arrives, it is allocated memory from a hole large enough to accommodate it
- Process exiting frees its partition, adjacent free partitions combined
- Operating system maintains information about:
   a) allocated partitions
   b) free partitions (hole)
- Considering the size of process as,
- Process 5=100MB, Processes 8=400MB, Process 2=200MB, Process 9=200MB, process 10=100MB, can the process 11=200MB be accommodated after process 5 terminates?

### **Partitions**

- Advantages
- 1. No Internal Fragmentation
- 2. No restriction on Degree of Multiprogramming
- 3. No Limitation on the size of the process
- Disadvantages
  - Causes External Fragmentation
  - Difficult to implement

### **Dynamic Storage-Allocation Problem and Strategies**

How to satisfy a request of size *n* from a list of free holes?

- First-fit: Allocate the first hole that is big enough (generally faster)
- Best-fit: Allocate the smallest hole that is big enough; must search entire list, unless ordered by size
  - Produces the smallest leftover hole
- Worst-fit: Allocate the *largest* hole; must also search entire list
  - Produces the largest leftover hole

First-fit and best-fit better than worst-fit in terms of speed and storage utilization

### **Allocations strategies: Examples**

Example: Given six memory partitions of 300 KB, 600 KB, 350 KB, 200 KB, 750 KB, and 125 KB (in order), how would the first-fit, best-fit, and worst-fit algorithms place processes of size 115 KB, 500 KB, 358 KB, 200 KB, and 375 KB (in order)? Rank the algorithms in terms of how efficiently they use memory.

#### Soln:

Partitions	First-Fit
M1=300 KB	P1
185KB	
M2=600 KB	P2
100KB	
M3=350 KB	P4
150KB	
M4=200 KB	
M5=750 KB	Р3
392KB	P5
17KB	
M6=125 KB	

Partitions	Best Fit
M1=300 KB	
M2=600 KB	P2
100KB	
M3=350 KB	
M4=200 KB	P4
M5=750 KB	P3
392KB	P5
17KB	
M6=125 KB	P1
10KB	

Partitions	Worst-Fit	
M1=300 KB		
M2=600 KB	Р3	
242KB		
M3=350 KB	P4	
150KB		
M4=200 KB		
M5=750 KB	P1	
635KB	P2	
135KB		
M6=125 KB		
P5 must wait		

Processes and their sizes
P1=115 KB P2=500 KB
P3=358 KB P4=200 KB
P5=375 KB

### **Fragmentation**

- Internal Fragmentation allocated memory may be slightly larger than requested memory; this size difference is memory internal to a partition, but not being used
- External Fragmentation total memory space exists to satisfy a request, but it is not contiguous
  - First fit statistical analysis reveals that given N allocated blocks (66% for example), another 0.5 N blocks (33% for example) lost to fragmentation
  - 1/3 of memory may be unusable -> 50-percent rule
    - Unusable memory = (0.5N)/(N+0.5N)=1/3

### Fragmentation (Cont.)

PES UNIVERSITY ONLINE

- Reduce external fragmentation by compaction
  - Shuffle memory contents to place all free memory together in one large block
  - Compaction is possible only if relocation is dynamic, and is done at execution time
  - I/O problem
    - Latch job in memory while it is involved in I/O
    - Do I/O only into OS buffers
